

SQL FOR DB2

Chapter 5

Logical Data Modeling

CHAPTER OBJECTIVES

- ① Explain logical data modeling
- ① Explain why data modeling is important
- ① Identify and explain the steps for developing a data model

INTRODUCTION TO LOGICAL DATA MODELING

- ⊙ Involves talking to end users and researching manuals, forms, and other documents that the organization uses
- ⊙ This information is first collected from the individual user or department perspective and then integrated into a unified, organization-wide data model
- ⊙ During the integration, conflicts, redundancy, and ambiguity need to be resolved
- ⊙ The logical data model should describe entities, attributes, relationships, and integrity constraints
- ⊙ The data model is stored in a data dictionary, which is a collection of documents, tables, diagrams, and other items that contain all the descriptions that are part of the model
- ⊙ Provides the basis for subsequent physical database design

STEPS FOR DEVELOPING A DATA MODELING

- ① Step 1: Identify Entities(Tables)
- ② Step 2: Determine Relationships Between Entities
- ③ Step 3: Determine Attributes(Columns)
- ④ Step 4: Determine the Primary Key for Each Entity
- ⑤ Step 5: Determine Foreign Key Rules
- ⑥ Step 6: Eliminate Redundancy in Tables using Normalization
- ⑦ Step 7: Determine Additional Integrity Constraints
- ⑧ Step 8: Determine Security Rules

STEP 1: IDENTIFY ENTITIES (TABLES)

- ① Entities are things about which facts need to be captured and stored
- ① Entities are usually nouns that could fall into the following categories: objects, events, places, and people
- ① Entities should have more than one row or instance
- ① When an entity is discovered, be sure to enter it in the data dictionary
- ① As entities are identified, also identify entity hierarchies

STEP 2: DETERMINE RELATIONSHIPS

- ⊙ Entities do not exist in isolation; they are interrelated
- ⊙ When a relationship is identified, document it and give it a name
- ⊙ Relationships can be recorded in textual, table form or an Entity Relationship Diagram(ERD)
- ⊙ In addition, for each relationship, its cardinality should be determined:
 - ⊙ One-to-one
 - ⊙ One-to-many
 - ⊙ Many-to-many
- ⊙ When identifying relationships, also determine the degree of each relationship

STEP 3: DETERMINE ATTRIBUTES (COLUMNS)

- ⦿ Determine which attributes are single-valued and which are multi-valued
- ⦿ Determine which attributes are time-dependent
- ⦿ Document each attribute with the following:
 - ⦿ Official name used in the data model
 - ⦿ Short description
 - ⦿ The source in the business process
 - ⦿ Allowable values (domain)
 - ⦿ Required or optional
 - ⦿ Default value
 - ⦿ Primary key, foreign key or candidate key

STEP 4: DETERMINE THE PRIMARY KEY

- ⦿ Each primary and candidate key must meet the following criteria:
 - ⦿ Candidate key values must be unique for each row in the table
 - ⦿ Candidate key values must never be missing or incomplete for a row
 - ⦿ Each candidate key must use no columns other than those necessary to identify a row uniquely
- ⦿ A primary key should also meet the following criteria:
 - ⦿ It should be meaningless, other than as an identifier
 - ⦿ A row's primary key value should never change
 - ⦿ There should be no practical limit to the number of primary key values available
 - ⦿ Only one primary key should be specified for each table

STEP 5: DETERMINE FOREIGN KEY RULES

- ⦿ The delete-update-insert rules between the primary and foreign keys in each relationship specify the way referential integrity will be enforced
- ⦿ Delete-Update-Insert rules:
 - ⦿ Reject the delete, update or insert
 - ⦿ Handle the delete, update or insert with a custom procedure
 - ⦿ Cascade the delete or update to all related dependent tables
 - ⦿ Set the related dependent foreign key value to null or default value
 - ⦿ On insert create a default row in the target table

STEP 6: NORMALIZE THE TABLES

- ⊙ Make certain that the entities do not contain redundant facts
- ⊙ One approach to eliminating redundancy is to check each table to see that it does not violate any of the rules of normalization
- ⊙ Another way to eliminate redundancy is to check all columns to see whether they can be derived from other columns

STEP 7: DETERMINE INTEGRITY CONSTRAINTS

- ⦿ Business rules must be accurate and complete, or the database may become contaminated
- ⦿ Determine the domain of each attribute: allowable values and allowable operations
 - ⦿ Format or picture checks
 - ⦿ Data type checks
 - ⦿ Range checks
 - ⦿ Limit checks
 - ⦿ Presence checks
 - ⦿ Spelling checks
 - ⦿ Consistency Checks
 - ⦿ Cross-system Consistency Checks

STEP 8: DETERMINE SECURITY RULES

- ① *Value-independent* rules, which are restrictions on tables, views, and columns based solely on the type of data, not on particular values
- ① *Value-dependent* rules, which are based on specific values
- ① *Statistical* rules, which limit the types of inferences that can be made about values in the database using statistical functions such as Sum and Count
- ① *Context-dependent* rules, which are defined in terms of functions or system values, such as time of day

CHAPTER SUMMARY

- ⦿ To complete a data model, you normally work on several steps at the same time, and you may need to repeat some steps to refine the model.
- ⦿ A process model is also developed in parallel with the data model. The process model references the data model, and vice versa.
- ⦿ The following steps are a guideline for developing a data model:
 - ⦿ Step 1. Identify Entities (Tables).
 - ⦿ Step 2. Determine relationships between entities.
 - ⦿ Step 3. Determine attributes (columns).
 - ⦿ Step 4. Determine the primary key for each entity.
 - ⦿ Step 5. Determine foreign key rules for each relationship.
 - ⦿ Step 6. Eliminate redundancy in tables using normalization.
 - ⦿ Step 7. Determine additional integrity constraints.
 - ⦿ Step 8. Determine security rules.
